Sprint 1

Name: Jay Khamthong

GitHub ID: jmkhamdevelops-cloud

Email: jmkhamdevelops@gmail.com

Group Name: Stock App

Branches I owned and worked on: *JaysNewDashboard* ← *dynamicDashboard* ← *newDashBoard* ← *JaysDashBoard*: These branches are iterations of my dashboard with *JaysNewDashboard* the final version that went into main.

AzureReady: This branch is for testing deployment to Azure

What you planned to do

- WebApp Deployment
  - Deploy Frontend and Backend as separate containers in Azure
  - Frontend should be able to talk to backend
- Implement dashboard main component
  - Create a component with stock data for reporting
- Implement react API calls
  - Create fetch calls to interact/communicate with backend endpoints

What you did not do

- WebApp Deployment cause a little bit of an issue where our database was not syncing. Because of this, I probably completed about 80% of getting it deployed before asking for help.
  - Aidan and I worked together to find what was wrong.
  - Aidan found that our database did not match what we had on Azure

Issues completed

- 80% of WebApp Deployment
  - Deploy Frontend and Backend as separate containers in Azure
  - Frontend should be able to talk to backend
- Implement dashboard main component
  - Create a component with **live** stock data for reporting
- Implement react API calls
  - fetched calls to interact/communicate with backend endpoint

Files and Branches I worked on

(Branch Iterations of my Activity)

JaysNewDashboard ← dynamicDashboard ← newDashBoard ← JaysDashBoard

- Frontend/package.json
    - React dependencies
- StockApp/Frontend/src/components/Dashboard.jsx
    - Final Branch has finished iteration
    - To see iterations follow branches I mentioned up top
- StockApp /Frontend/src/Table.css
    - I added this to our repository for styling of the table in the dashboard
- **AzureReady (Branch)**
    - **This branch took up alot of my time because it would not deploy properly**
    - This branch is not part of our main project, but it has several files and commits pertaining to our deployment on Azure
    - Backend/config/deployment.py
        - This was a file I was considering using to distinguish between local development and production development
        - I came across this on a YouTube tutorial of how to deploy
    - .github/workflows/azureready_cosc540-backend-stockapp.yml
        - This is the GitHub actions file that is needed for deployment.
            - I spent quite a bit of time troubleshooting our issue on Azure with this file
    - Backend/. production
        - This is needed for Azure deployment
    - Backend/config/wsgi.py
        - I wanted to implement this so that our app can auto switch between local and Azure deployment
    - Backend/manage.py
        - This was also needed in my deployment/version of our Azure deployment

Use of AI and/or 3rd party software

- I used AI for troubleshooting and ideas of how to start my code. I did not just copy pasted but used bits of it and modified to my needs.
- 3rd party code I used are from:
    - I am fairly new to react and needed help from tutorials and one I used for my graph is Chart Tutorials. Once I understood what is needed, I modified the tutorial to our needs.
    - Finally, I used and watched several tutorials on YouTube for inspiration, ideas and how-to's to grasp what I needed to do.

What you accomplished

Dynamic Dashboard

- I added the line chart to our dashboard along with several cards of an account's current stocks.
- The line chart is currently using static data, but the idea is to show the trend of the user's investment amount, profit included
    - There were other charts that were initially on there, but we decided to keep it simple.
- All these items on this dashboard are using dynamic data from our external API
- I am also showing we can grab data from our back end.

Azure Deployment

- A lot of time was spent on this, trying to deploy our application to Azure.
- We can deploy locally but when deployed to Azure, things would not work right.
- What I accomplished most was understanding how to deploy applications to Azure, both static websites and back-end apps using Web Services.
- I was able to get our application to build using Azure's CI/CD pipeline using the .yaml file
    - I have never worked on CI/CD, GitHub before until this project
- Even though I could not deploy it 100%, my accomplishments in following tutorials and research will be useful for further sprints.
